Why Machine Learning: Early Artificial Intelligence

Early artificial intelligence techniques used introspection to codify knowledge, often in the form of rules.

Expert systems, one of the most notable applications of traditional AI, were entirely based on the competence of experts.

This has two major drawbacks:

- Need of an expertise to understand and explain the rules
- Bias introduced by the expert

Why Machine Learning: What has Changed

Now terabytes of data available.

Makes it impossible to understand such volumes of data, organize them using manually-crafted rules.

Triggered a major move to empirical and statistical techniques.

Applications in natural language processing, medicine, banking, online shopping, image recognition, etc.

The success of companies like Google, Facebook, Amazon, and Netflix, not to mention Wall Street firms and industries from manufacturing and retail to healthcare, is increasingly driven by better tools for extracting meaning from very large quantities of data. 'Data Scientist' is now the hottest job title in Silicon Valley.

– Tim O'Reilly (2012)

Some Definitions

- 1 Machine learning always starts with **datasets**: a collection of objects or observations.
- 2 Machine-learning algorithms can be classified along two main lines: **supervised** and **unsupervised** classification.
- 3 Supervised algorithms need a **training set**, where the objects are described in terms of attributes and belong to a known class or have a known output.
- 4 The performance of the resulting classifier is measured against a **test set**.
- 5 We can also use N -fold cross validation, where the test set is selected randomly from the training set N times, usually 10.
- 6 Unsupervised algorithms consider objects, where no class is provided.
- 7 Unsupervised algorithms learn regularities in datasets.

A Dataset: *Salammbô*

A corpus is a collection – a body – of texts.

Supervised Learning: Regression

Letter count from *Salammbô* in French

Models

We will assume that datasets are governed by functions or models.
For instance given the set:

$$\{(\mathbf{x}_i, y_i) | 0 < i \leq N\},$$

there exists a function such that:

$$f(\mathbf{x}_i) = y_i.$$

Supervised machine learning algorithms will produce hypothesized functions or models fitting the data.

The predicted value is denoted:

$$f(\mathbf{x}_i) = \hat{y}_i.$$

to make a difference with the observed value: y_i .

Selecting a Model

Often, multiple models can fit a dataset:
Three polynomials of degree: 1, 8, and 9

A general rule in machine learning is to prefer the simplest hypotheses, here the lower polynomial degrees.

Supervised Learning: Regression and Classification

Given the dataset, $\{(\mathbf{x}_i, y_i) | 0 < i \leq N\}$ and a model f :

- Classification: $f(\mathbf{x}) = y$ is discrete,
- Regression: $f(\mathbf{x}) = y$ is continuous.

Table: A dataset. Adapted and simplified from the original article that described how to apply logistic regression to classification by Joseph Berkson, Application of the Logistic Function to Bio-Assay. *Journal of the American Statistical Association* (1944).

Regression: Another Model, the Logistic Curve (Verhulst)

Mémoires de l'Académie.

Tome XVIII.

Fitting the Logistic Curve

Berkson fitted the curve to the data using the logarithm of the dose. He obtained:

$$\frac{1}{1 + e^{-5.659746x + 10.329884}}$$

Loss

Another word for error measurement (also called optimization criterion)
 The loss function is defined as $L(y, \hat{y})$ with $\hat{y} = h(\mathbf{x})$, where \mathbf{x} is the vector of attributes, h the classifier, and y , the correct value (also called the truth or ground truth).

Common losses:

Absolute value loss	$L_1(y, \hat{y})$	=	$ y - \hat{y} $
Squared error loss	$L_2(y, \hat{y})$	=	$(y - \hat{y})^2$
0/1 loss	$L_{0/1}(y, \hat{y})$	=	0 if $y = \hat{y}$ else 1
Binary crossentropy	$BCE(y, \hat{y})$	=	$-\log \hat{y}$ if $y = 1$ else $-\log(1 - \hat{y})$
Categorical crossentropy	$CE(y, \hat{y})$	=	$-y \cdot \log \hat{y}$, where we represent y as a unit vector.

Logistic Loss

The logistic loss, or binary cross entropy, or negative log-likelihood, is defined as

$$L(\hat{y}) = -\log \hat{y}$$

in blue compared with the squared error loss in red

$$(1 - \hat{y})^2,$$

where \hat{y} is a probability ranging from 0 to 1.

Empirical Loss

We compute the empirical loss of a classifier h on a set of examples E using the reduction formula:

$$\text{Loss}(L, E, h) = \frac{1}{N} \sum_E L(y, h(x)).$$

For continuous functions:

$$\text{Loss}(L, E, h) = \frac{1}{N} \sum_E (y - h(x))^2.$$

General Observations on Loss

- Depending on their type, errors can have different impacts.
- Imagine a smoke detector that predicts fire.
- Equivalent to a classifier that uses input data from sensors and classifies them as *fire* and *nonfire*.
- The loss function is defined as $L(y, \hat{y})$ with $\hat{y} = h(\mathbf{x})$, where \mathbf{x} is the vector of attributes, h the classifier, and y , the correct value.
- The cost of $L(\text{fire}, \text{nonfire})$ is much higher than $L(\text{nonfire}, \text{fire})$.
- $L(\text{fire}, \text{fire}) = L(\text{nonfire}, \text{nonfire}) = 0$

Unsupervised Learning: Clustering

No class is given:

Objects, Attributes, and Classes. After Quinlan (1986)

Object	Attributes				Class
	Outlook	Temperature	Humidity	Windy	
1	Sunny	Hot	High	False	N
2	Sunny	Hot	High	True	N
3	Overcast	Hot	High	False	P
4	Rain	Mild	High	False	P
5	Rain	Cool	Normal	False	P
6	Rain	Cool	Normal	True	N
7	Overcast	Cool	Normal	True	P
8	Sunny	Mild	High	False	N
9	Sunny	Cool	Normal	False	P
10	Rain	Mild	Normal	False	P
11	Sunny	Mild	Normal	True	P
12	Overcast	Mild	High	True	P
13	Overcast	Hot	Normal	False	P
14	Rain	Mild	High	True	N

Synonyms

Different names for the same thing. Here are few synonyms:

- Object, observation, datapoint, sample, instance, event;
- Attribute, feature, predictor, parameter, variable;
- Class, label, output, response, target.

Statistics and machine learning have a large overlap, but a different vocabulary

Glossary from Robert Tibshirani (prof. in statistics and statistical learning)

Classifying Objects with Decision Trees. After Quinlan (1986)

Matrix Notation

- A feature vector (predictors or attributes): \mathbf{x} , and feature matrix: \mathbf{X} ;
- The class: y and the class vector: \mathbf{y} ;
- The predicted class (response): \hat{y} , and predicted class vector: $\hat{\mathbf{y}}$

$$\mathbf{X} = \begin{bmatrix} \text{Sunny} & \text{Hot} & \text{High} & \text{False} \\ \text{Sunny} & \text{Hot} & \text{High} & \text{True} \\ \text{Overcast} & \text{Hot} & \text{High} & \text{False} \\ \text{Rain} & \text{Mild} & \text{High} & \text{False} \\ \text{Rain} & \text{Cool} & \text{Normal} & \text{False} \\ \text{Rain} & \text{Cool} & \text{Normal} & \text{True} \\ \text{Overcast} & \text{Cool} & \text{Normal} & \text{True} \\ \text{Sunny} & \text{Mild} & \text{High} & \text{False} \\ \text{Sunny} & \text{Cool} & \text{Normal} & \text{False} \\ \text{Rain} & \text{Mild} & \text{Normal} & \text{False} \\ \text{Sunny} & \text{Mild} & \text{Normal} & \text{True} \\ \text{Overcast} & \text{Mild} & \text{High} & \text{True} \\ \text{Overcast} & \text{Hot} & \text{Normal} & \text{False} \\ \text{Rain} & \text{Mild} & \text{High} & \text{True} \end{bmatrix}; \mathbf{y} = \begin{bmatrix} \text{N} \\ \text{N} \\ \text{P} \\ \text{P} \\ \text{P} \\ \text{N} \\ \text{P} \\ \text{N} \\ \text{P} \\ \text{P} \\ \text{P} \\ \text{P} \\ \text{P} \\ \text{N} \end{bmatrix}$$

Decision Trees and Classification

- Each object is defined by an attribute vector (or feature vector or predictors) $\{A_1, A_2, \dots, A_v\}$
- Each object belongs to one class $\{C_1, C_2, \dots, C_n\}$
- The attributes of the examples are:
 $\{Outlook, Temperature, Humidity, Windy\}$ and the classes are:
 $\{N, P\}$.
- The nodes of the tree are the attributes.
- Each attribute has a set of possible values. The values of *Outlook* are $\{sunny, rain, overcast\}$
- The branches correspond to the values of each attribute
- The optimal tree corresponds to a minimal number of tests

Entropy, Decision Trees, and Classification

- Decision trees are useful devices to classify objects into a set of classes.
- Shannon's entropy is a quantification of distribution diversity in a set of symbols
- It can help us learn automatically decision trees from a set of data.
- The algorithm is one of the simplest machine-learning techniques to obtain a classifier.

Inducing (Learning) Decision Trees Automatically: ID3

It is possible to design many trees that classify the objects successfully

An efficient decision tree uses a minimal number of tests.

In the decision tree:

- Each example is defined by a finite number of attributes.
- Each node in the decision tree corresponds to an attribute that has as many branches as the attribute has possible values.

At the root of the tree, the condition must be the most discriminating, that is, have branches gathering most positive examples while others gather negative examples.

ID3 (Quinlan 1986)

Each attribute scatters the set into as many subsets as there are values for this attribute.

In the dataset, we have nine positive examples and five negative ones,

At each decision point, the “best” attribute has the maximal separation power, the maximal information gain

Better Root?

How can we measure this?

Answer: Entropy or Gini impurity

Entropy (I)

Information theory models a text as a sequence of symbols.

Let x_1, x_2, \dots, x_N be a discrete set of N symbols representing the characters.

The **information content** of a symbol is defined as

$$I(x_i) = -\log_2 P(x_i) = \log_2 \frac{1}{P(x_i)},$$

where

$$P(x_i) = \frac{\text{Count}(x_i)}{\sum_{j=1}^n \text{Count}(x_j)}.$$

Information content of:

- P : $-\log_2 \frac{9}{14} = 0.6374$
- N : $-\log_2 \frac{5}{14} = 1.4854$

Entropy (II)

Entropy, the average information content, is defined as:

$$H(X) = - \sum_{x \in X} P(x) \log_2 P(x),$$

By convention: $0 \log_2 0 = 0$.

Entropy of the dataset:

$$I(P, N) = -\frac{9}{14} \log_2 \frac{9}{14} - \frac{5}{14} \log_2 \frac{5}{14} = 0.940.$$

Entropy Examples

In the three child nodes:

$$\text{sunny : } I(P_1, N_1) = -\frac{2}{5} \log_2 \frac{2}{5} - \frac{3}{5} \log_2 \frac{3}{5} = 0.971.$$

$$\text{overcast : } I(P_2, N_2) = 0.0$$

$$\text{rain : } I(P_3, N_3) = -\frac{3}{5} \log_2 \frac{3}{5} - \frac{2}{5} \log_2 \frac{2}{5} = 0.971$$

Understanding the Entropy

For a two-class set, let us denote:

$$x = \frac{p}{p+n} \text{ and } \frac{n}{p+n} = 1-x.$$

$$I(x) = -x \log_2 x - (1-x) \log_2 (1-x) \text{ with } x \in [0, 1].$$

The entropy reaches a maximum when there are as many positive as negative examples in the dataset. It is minimal when the set consists of either positive or negative examples.

Gini Impurity

Gini impurity is an alternative to entropy:

$$G(X) = - \sum_{x \in X} P(x)(1 - P(x)),$$

For a two-class set, we set:

$$\begin{aligned} 2G(x) &= 2(x(1-x) + (1-x)x) \text{ with } x \in [0, 1]. \\ &= 4x(1-x) \end{aligned}$$

ID3 (Quinlan 1986)

ID3 uses the entropy to select the best attribute to be the root of the tree and recursively the next attributes of the resulting nodes.

The entropy of a two-class set p and n is:

$$I(p, n) = -\frac{p}{p+n} \log_2 \frac{p}{p+n} - \frac{n}{p+n} \log_2 \frac{n}{p+n}.$$

The weighted average of all the nodes below an attribute A is:

$$E(A) = \sum_{i=1}^v \frac{p_i + n_i}{p+n} I\left(\frac{p_i}{p_i + n_i}, \frac{n_i}{p_i + n_i}\right).$$

The information gain is defined as $I(p, n) - E(A)$ (or $I_{\text{before}} - I_{\text{after}}$)

This measures the separating power of an attribute: the more the gain, the better the attribute.

Example

The entropy of the Quinlan dataset is:

$$I(p, n) = -\frac{9}{14} \log_2 \frac{9}{14} - \frac{5}{14} \log_2 \frac{5}{14} = 0.940.$$

Outlook has three values: *sunny*, *overcast*, and *rain*. The entropies of the corresponding subsets are:

$$\text{sunny : } I(p_1, n_1) = -\frac{2}{5} \log_2 \frac{2}{5} - \frac{3}{5} \log_2 \frac{3}{5} = 0.971.$$

$$\text{overcast : } I(p_2, n_2) = 0.0$$

$$\text{rain : } I(p_3, n_3) = -\frac{3}{5} \log_2 \frac{3}{5} - \frac{2}{5} \log_2 \frac{2}{5} = 0.971.$$

Gain(Outlook) is then $0.940 - \frac{5}{14} \times 0.971 - \frac{5}{14} \times 0.971 = 0.246$, the highest possible among the attributes.

We have *Gain(Temperature)* = 0.029, *Gain(Humidity)* = 0.151 and *Gain(Windy)* = 0.048.

Inducing Decision Trees Automatically: ID3

The algorithm to build the decision tree is simple:

- ❶ The information gain is computed on the dataset for all attributes in the set of attributes, SA .
- ❷ The attribute with the highest gain is selected to be the root of the tree:

$$A = \arg \max_{a \in SA} I(n, p) - E(a).$$

- ❸ The dataset is split into v subsets $\{N_1, \dots, N_v\}$, where the value of A for the objects in N_i is A_i .
- ❹ For each subset, a corresponding node is created below the root.
- ❺ This process is repeated recursively for each node of the tree with the subset it contains until all the objects of the node are either positive or negative.

For a training set of N instances each having M attributes, ID3's complexity to generate a decision tree is $O(NM)$.

Decision Tree Learning Algorithm (From the Textbook)

```

1: function DTL(examples, attributes, parent_examples) returns a
   tree
2:   if examples is empty then
3:     return PluralityValue(parent_examples)
4:   else if all examples have the same classification then
5:     return the classification
6:   else if attributes is empty then
7:     return PluralityValue(examples)
8:   else
9:      $A \leftarrow \arg \max_{a \in \text{attributes}} \text{InformationGain}(a, \text{examples})$ 
10:    tree  $\leftarrow$  a new decision tree with root test A
11:    for all  $v_k \in A$  do
12:      exs  $\leftarrow \{e : e \in \text{examples} \text{ and } e.A = v_k\}$ 
13:      subtree  $\leftarrow$  DTL(exs, attributes – A, examples)
14:      add a branch to tree with label  $\{A = v_k\}$  and subtree
   subtree
return tree

```

Learning Curve

The classical evaluation technique uses a training set and a test set. Generally, the larger the training set, the better the performance. This can be visualized with a learning curve. From the textbook, Stuart Russell and Peter Norvig, *Artificial Intelligence*, 3rd ed., 2010, page 703.

Overfitting

- When two classifiers have equal performances on a specific test set, the simplest one is supposed to be more general
- A small decision tree is always preferable to a larger one.
- Complex classifiers may show an overfit to the training data and have poor performance when the dataset changes.
- In the case of decision trees, overfits show with deep trees and when numerous leaves have few examples.

Pruning Trees

Decision tree pruning consists in removing and merging leaves with few objects, for instance one or two.

To prune the tree:

- 1 Generate the complete decision tree
- 2 Consider the nodes that have only leaves as children and merge the leaves if the information gain is below a certain threshold.
- 3 To determine the threshold, we use a significance test.

This is the χ^2 pruning.

Contingency Tables

Example: A set of 12 positive and 8 negative examples. (A disease for instance flu or noflu)

Let us compare two attributes:

- Attribute 1 with three values: $\{v_1^1, v_1^2, v_1^3\}$ (for instance, size)
- Attribute 2 with three values: $\{v_2^1, v_2^2, v_2^3\}$ (for instance, temperature)

Contingency tables are devices to visualize frequency distributions.

Attribute 1		v_1^1	v_1^2	v_1^3	
	Positive	6	3	3	12 (60%)
	Negative	4	2	2	8 (40%)
	Total	10	5	5	20 (100%)

Attribute 2		v_2^1	v_2^2	v_2^3	
	Positive	1	1	10	12 (60%)
	Negative	8	0	0	8 (40%)
	Total	9	1	10	20 (100%)

Significance Test

An attribute with no significance would have the same proportions of positive and negative examples before and after the test.

Proportions before, for instance 12 and 8:

$$\frac{p}{p+n} \quad \text{and} \quad \frac{n}{p+n}$$

Proportions after, for v_k , a value of the attribute:

$$\frac{p_k}{p_k + n_k} \quad \text{and} \quad \frac{n_k}{p_k + n_k}$$

The expected values of a nonsignificant attribute (null hypothesis) are:

$$\hat{p}_k = \frac{p}{p+n} \times (p_k + n_k) \quad \hat{n}_k = \frac{n}{p+n} \times (p_k + n_k)$$

Example

Contingency tables with the observed and expected frequencies in three groups, in blue and red, respectively.

	Class	Group 1		Group 2		Group 3		
Attribute 1 (v_1)		v_1^1	\hat{v}_1^1	v_1^2	\hat{v}_1^2	v_1^3	\hat{v}_1^3	
	Positive	6	6	3	3	3	3	12 (60%)
	Negative	4	4	2	2	2	2	8 (40%)
	Total	10		5		5		20 (100%)
Attribute 2 (v_2)		v_2^1	\hat{v}_2^1	v_2^2	\hat{v}_2^2	v_2^3	\hat{v}_2^3	
	Positive	1	5.4	1	0.6	10	6	12 (60%)
	Negative	8	3.6	0	0.4	0	4	8 (40%)
	Total	9		1		10		20 (100%)

The total deviation for an attribute with values $v_1..v_d$ is:

$$\Delta = \sum_{k=1}^d \frac{(p_k - \hat{p}_k)^2}{\hat{p}_k} + \frac{(n_k - \hat{n}_k)^2}{\hat{n}_k}$$

Pruning Trees (II)

- The null hypothesis corresponds to an irrelevant attribute: $\Delta = 0$.
- Δ values are distributed according to the χ^2 distribution
- If v is the number of values of an attribute, the degree of freedom is $v - 1$
- The corresponding χ^2 distributions can be found in statistical tables.
 - For three degrees of freedom:
10%: 6.25, 5%: 7.81, 1%: 11.34, 1‰: 16.27
 - The significance level is usually 5%
- An alternate pruning method is to modify the termination condition of the algorithm:
 - We stop when the information gain is below a certain threshold

Dealing with Real Data

- Unknown attribute values (imputation): Use the most frequent value of the attribute or all the values;
- Attributes with many values (large attribute domains): Difficult to handle for decision trees. The book suggests to use the gain ratio:

$$\frac{\text{Information gain}}{\text{Information value}}, \text{ where Information value} = - \sum_{i=1}^v \frac{p_i + n_i}{p + n} \log_2 \frac{p_i + n_i}{p + n}$$

- Numerical attributes: Find the binary split point that maximizes the information gain
- Numerical output: Regression tree

Evaluation

- The standard evaluation procedure is to train the classifier on a training set and evaluate the performance on a test set.
- When we have only one set, we divide it in two subsets: the training set and the test set (or holdout data).
- The split can be 90–10 or 80–20
- This often optimizes the classifier for a specific test set and creates an overfit

A frequent practice is to have a **validation set** (also called development set) and carry out intermediate evaluations on it.

Cross Validation

- A N -fold cross validation mitigates the overfit
- The set is partitioned into N subsets, $N = 5$ for example, one of them being the test set (red) and the rest the training set (gray).
- The process is repeated N times with a different test set: N folds

At the extreme, **leave-one-out cross-validation**.

Model Selection

- Validation can apply to one classification method
- We can use it to select a classification method and its parametrization.
- Needs three sets: training set, validation (development) set, and test set.

Evaluation

There are different kinds of measures to evaluate the performance of machine learning techniques, for instance:

- Precision and recall in information retrieval and natural language processing;
- The *receiver operating characteristic* (ROC) in medicine.

	Positive examples: P	Negative examples: N
Classified as P	True positives: A	False positives: B
Classified as N	False negatives: C	True negatives: D

More on the receiver operating characteristic here: http://en.wikipedia.org/wiki/Receiver_operating_characteristic

Recall, Precision, and the F-Measure

The **accuracy** is $\frac{|AUD|}{|PUN|}$.

Recall measures how much relevant examples the system has classified correctly, for P :

$$\text{Recall} = \frac{|A|}{|A \cup C|}.$$

Precision is the accuracy of what has been returned, for P :

$$\text{Precision} = \frac{|A|}{|A \cup B|}.$$

Recall and precision are combined into the **F-measure**, which is defined as the harmonic mean of both numbers:

$$F = \frac{2 \cdot \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}.$$

Measuring Quality: The Confusion Matrix

A task in natural language processing: Identify the parts of speech (POS) of words.

Example: *The can rusted*

- The human: *The*/art (DT) *can*/noun (NN) *rusted*/verb (VBD)
- The POS tagger: *The*/art (DT) *can*/modal (MD) *rusted*/verb (VBD)

↓Correct	Tagger →									
	DT	IN	JJ	NN	RB	RP	VB	VBD	VBG	VBN
DT	99.4	0.3	—	—	0.3	—	—	—	—	—
IN	0.4	97.5	—	—	1.5	0.5	—	—	—	—
JJ	—	0.1	93.9	1.8	0.9	—	0.1	0.1	0.4	1.5
NN	—	—	2.2	95.5	—	—	0.2	—	0.4	—
RB	0.2	2.4	2.2	0.6	93.2	1.2	—	—	—	—
RP	—	24.7	—	1.1	12.6	61.5	—	—	—	—
VB	—	—	0.3	1.4	—	—	96.0	—	—	—
VBD	—	—	0.3	—	—	—	—	94.6	—	—
VBG	—	—	2.5	4.4	—	—	—	—	98.0	—
VBN	—	—	4.6	—	—	—	—	4.3	—	—

ARFF: The Weka Data Format

Storing Quinlan's dataset in Weka's attribute-relation file format (ARFF)

<http://weka.wikispaces.com/ARFF>:

```
@relation weather.symbolic
```

```
@attribute outlook {sunny, overcast, rainy}
```

```
@attribute temperature {hot, mild, cool}
```

```
@attribute humidity {high, normal}
```

```
@attribute windy {TRUE, FALSE}
```

```
@attribute play {yes, no}
```

```
@data
```

```
sunny,hot,high,FALSE,no
```

```
sunny,hot,high,TRUE,no
```

```
overcast,hot,high,FALSE,yes
```

```
rainy,mild,high,FALSE,yes
```

```
rainy,cool,normal,FALSE,yes
```

```
rainy,cool,normal,TRUE,no
```

```
overcast,cool,normal,TRUE,yes
```

Entropy of a Text

The entropy of the text is

$$\begin{aligned}
 H(X) &= - \sum_{x \in X} P(x) \log_2 P(x). \\
 &= -P(A) \log_2 P(A) - P(B) \log_2 P(B) - \dots \\
 &\quad - P(Z) \log_2 P(Z) - P(\grave{A}) \log_2 P(\grave{A}) - \dots \\
 &\quad - P(\ddot{Y}) \log_2 P(\ddot{Y}) - P(\text{blanks}) \log_2 P(\text{blanks}).
 \end{aligned}$$

Entropy of Gustave Flaubert's *Salammbô* in French is $H(X) = 4.39$.

Cross-Entropy

The cross entropy of M on P is defined as:

$$H(P, M) = - \sum_{x \in X} P(x) \log_2 M(x),$$

where typically:

- The model distribution M is learned from a training set;
- The P distribution is obtained from a test set.

We have the inequality $H(P) \leq H(P, M)$.

The difference is called the **Kullback-Leibler divergence**.

Example of Kullback-Leibler divergence.

- The model, M , *Salammbo*, chapters 1-14, text in French
- The test sets we will evaluate, P , with their entropy $H(P)$ and cross entropy, $H(P, M)$:
 - 1 *Salammbo*, chapters 15, text in French
 - 2 *Notre Dame de Paris*: text in French
 - 3 *Nineteen Eighty-Four*: text in English

Datasets			Entropy	Cross entr.	Diff.
M	<i>Salammbo</i> , chaps. 1-14	training set	4.39481	4.39481	0.0
P	<i>Salammbo</i> , chapt. 15	test set	4.34937	4.36074	0.01137
P	<i>Notre Dame de Paris</i>	test set	4.43696	4.45507	0.01811
P	<i>Nineteen Eighty-Four</i>	test set	4.35922	4.82012	0.46090
